# **Hospital Management**

## Description

## Objective:

To work with a Spring Core application using annotations, autowiring, and bean configuration concepts.

## **Concept Explanation:**

- 1. **Autowiring** in Spring automatically wires beans together based on dependency types.
- 2. **Bean configuration** involves defining and configuring application components (beans) and their dependencies, through XML-based configuration or annotations.

## **Concept Implementation:**

- Autowiring is utilized to automatically inject dependencies, such as the Document object, into the constructors of the NewYorkHospital and LosAngelesHospital classes, simplifying the configuration and management of dependencies.
- Bean configuration is achieved using the @Configuration and @Bean annotations in the AppConfig class, where methods annotated with @Bean provide instances of Document objects for New York and Los Angeles patients, facilitating easy bean creation and management within the Spring application context.

Create a simple simulation for the workflow of a hospital's patient registration and treatment process. The Head Hospital sets rules for Regional Hospitals on how to process patient documents and provide treatment.
